Quaternary Fault and Fold Database of the United States

As of January 12, 2017, the USGS maintains a limited number of metadata fields that characterize the Quaternary faults and folds of the United States. For the most up-to-date information, please refer to the interactive fault map.

Washington fault zone, Sullivan Draw section (Class A) No. 1004c

Last Review Date: 1997-04-26

Compiled in cooperation with the Arizona Geological Survey

Synopsis	**General:** The Washington fault is a long, north- to northeast-trending fault zone with substantial Cenozoic normal displacement that straddles the western margin of the Colorado Plateaus province. It extends from the Shivwitz Plateau into the St. George basin in southern Utah. The fault zone has generated two prominent, west-facing bedrock escarpments in the southern St. George basin as a result of several hundred meters of normal displacement. The high, linear escarpments are formed by the two faults and its morphology suggests that this part of the fault zone has been fairly active during the Quaternary. Pleistocene deposits

	are faulted in a few places, but no definitive evidence of Holocene faulting has been discovered. Farther south, the Washington fault zone forms the westernmost of several grabens that cut the Shivwitz Plateau. The fault zone has a moderately high, west-facing escarpment and a narrow, shallow graben on the plateau; vertical displacement across the fault zone is less than 100 m. Along this part of the fault zone, upper Pleistocene deposits are displaced by a few meters, and Holocene deposits are not faulted. **Sections:** This fault has 3 sections. The sections (northern, Mokaac, and Sullivan Draw) are defined on the basis of structural geometry and geomorphic expression of the fault zone. The northern section encompasses the main Washington fault zone from the pass between Seegmiller and Wolf Hole Mountains north to the Utah border; this section was called the Washington fault by Billingsley (1990 #2079; 1992 #2077). The Mokaac section is subparallel with and northwest of the Washington section in the southern St. George basin. It was called the Mokaac Wash segment by Menges and Pearthree (1983 #2073) and the Mokaac fault by Billingsley 1990 #2079; 1992 #2077). It merges with the Washington section about 5 km south of the Utah border. The Sullivan Draw section is farther south on the Shivwitz Plateau, and total displacement across the fault is much less. Along much of this section, there is a companion, east-dipping fault to the west of the Washington fault. Together, they form the Sullivan graben of Billingsley (1991 #2081; 1991 #2082).
Name comments	**General:** **Section:** This section name applies to the part of the Washington fault on the Shivwitz Plateau south of the pass between Seegmiller and Wolf Hole Mountains. This section includes the main Washington fault zone and east-dipping faults that form the western margin of the Sullivan graben.
County(s) and State(s)	MOHAVE COUNTY, ARIZONA
Physiographic province(s)	COLORADO PLATEAUS
Reliability of location	Good Compiled at 1:250,000 scale. *Comments:* Mapped at 1:24,000 scale; the traces were transferred to 1:250,000-scale topographic base map for digitization.

Geologic setting	The north- to northeast-trending Washington fault zone straddles the margin of the Colorado Plateaus province in northwestern Arizona. Paleozoic rocks are displaced vertically by several hundred meters across each of the two major fault strands in the southern St. George basin. Tertiary basalt is also displaced by substantial amounts across these fault strands, and upper Quaternary alluvium is displaced several meters (Billingsley, 1990 #2079; 1992 #2077). Vertical displacement of Paleozoic rocks is less than about 100 m across the southern section of the fault on the Shivwitz Plateau; upper Pleistocene to Holocene (?) alluvial deposits are displaced by as much as 3 m along this section of the fault. The fault has an estimated maximum throw of 750 m in Arizona, but displacement decreases northward in Utah. The fault displaces pre-existing geologic structures and has normal-drag and reverse-drag folding genetically associated with it (Anderson and Christenson, 1989 #828).
Length (km)	This section is 34 km of a total fault length of 72 km.
Average strike	N3°W (for section) versus N23°E,N11°E,N11°E (for whole fault)
Sense of movement	Normal *Comments:* Based on regional relations and normal displacement of bedrock and alluvium across the fault zone.
Dip Direction	W; E *Comments:* Based on the topographic expression of faulting and structural relations; the main fault zone dips west and antithetic faults dip east.
Paleoseismology studies	
Geomorphic expression	Faulting is expressed as a moderately high, fairly steep, curvilinear, west-facing escarpment and a lower, east-facing scarp formed in Paleozoic bedrock on the Shivwitz Plateau. Low alluvial fault scarps (displacements of 3 m or less) have been mapped in several places along this segment, but their morphologies have not been documented.
Age of faulted surficial	Paleozoic, late Pleistocene. The geology of the fault zone was mapped by Billingsley (1990 #2079; 1990 #2080; 1991 #2081;

deposits	1991 #2082; 1992 #2077).
Historic earthquake	
Most recent prehistoric deformation	late Quaternary (<130 ka) *Comments:* Based on the estimated age of displaced deposits.
Recurrence interval	
Slip-rate category	Less than 0.2 mm/yr
Date and Compiler(s)	1997 Philip A. Pearthree, Arizona Geological Survey
