Quaternary Fault and Fold Database of the United States

As of January 12, 2017, the USGS maintains a limited number of metadata fields that characterize the Quaternary faults and folds of the United States. For the most up-to-date information, please refer to the <u>interactive fault map</u>.

Eastern Dixie Valley fault (Class A) No. 1171

Last Review Date: 2000-08-21

citation for this record: Lidke, D.J., compiler, 2000, Fault number 1171, Eastern Dixie Valley fault, in Quaternary fault and fold database of the United States: U.S. Geological Survey website, https://earthquakes.usgs.gov/hazards/qfaults, accessed 12/14/2020 02:17 PM.

Synopsis	This discontinuous, northeast-striking fault zone consists of faults
	that place bedrock against Pleistocene piedmont-slope deposits
	and faults that form scarps on piedmont-slope deposits as young
	as late Quaternary age. Although there appears to be abundant
	evidence for Quaternary movement along the fault zone,
	estimates of offsets along individual fault strands or along the
	entire zone have not been reported. Basal fault facets are absent
	along the range-front adjacent to this fault zone and the absence
	of basal fault facets suggests relatively low Quaternary slip rates.
	The fault zone has not been studied in detail. The principal
	sources of data include geologic mapping, reconnaissance
	photogeologic mapping, and reconnaissance geomorphic study of
	fault scarps.
Name	The unnamed northern section refers to faults mapped by Willden
comments	and Speed (1968 #4370; 1974 #3645) and Dohrenwend and

	others (1992 #283) along parts of the western flanks of the
	southern Augusta and northern Clan Alpine Mountains, and refers
	to the northern part of the Eastern Dixie Valley fault zone as
	shown by dePolo (1998 #2845). Section extends from just south
	of 40? 00' latitude, along the Augusta Mountains, southwest to
	about Shoshone Creek, along the Clan Alpine Mountains.
	Fault ID: Refers to fault MI1 of dePolo (1998 #2845).
County(s) and State(s)	CHURCHILL COUNTY, NEVADA
Physiographic province(s)	BASIN AND RANGE
Reliability of	Good
location	Compiled at 1:250,000 scale.
	<i>Comments:</i> Location is from 1:250,000-scale map of Dohrenwend
	and others (1992 #283), which shows mapping based on
	photogeologic analysis of 1:58,000-nominal-scale, color-infrared
	photography transferred directly to 1:100,000-scale topographic
	maps enlarged to the scale of the photographs; these maps were
	then reduced and compiled at 1:250,000-scale.
Geologic setting	This northeast-striking zone of faults consists of two groups of
Geologie seeing	faults along the western flanks of the Augusta and Clan Alpine
	Mountains. These mountain ranges expose bedrock that consists
	mainly of Tertiary volcanic and volcaniclastic rocks (Willden and
	Speed 1968 #4370: 1974 #3645) Some faults of the zone place
	Tartiary hadroak of the mountain ranges against Disistence

Length (km)	surficial deposits of the adjacent Dixie Valley, but apparently do not have the geomorphic expression of range-front faults (Dohrenwend and others, 1992 #283). Those faults that involve bedrock, as well as several west-facing scarps on Pleistocene, piedmont-slope deposits, consistently indicate down-to-the-west offsets that probably reflect continued Quaternary uplift of the mountain ranges relative to the adjacent northern part of the Dixie Valley. Although there appears to be abundant evidence for Quaternary movement along the fault zone, estimates of offsets along individual faults or along the entire zone have not been reported.

Sense of movement	Normal <i>Comments:</i> Not specifically reported, however, west-facing scarps on piedmont deposits, as well as down-to-the-west bedrock faults, consistently indicate down-to-the-west fault offsets, which in this extensional regime probably reflects principally normal, dip-slip movement along west-dipping faults.
Dip Direction	NE <i>Comments:</i> Not reported, but probably steep, based on dip measurements of other Quaternary faults in localities nearby and elsewhere in the Basin and Range Province
Paleoseismology studies	
Geomorphic expression	Faults define a zone of deformation along parts of the western flanks of the Augusta and Clan Alpine Mountains and the adjacent eastern piedmont slope of the Dixie Valley. Locally the fault juxtaposes Pleistocene piedmont-slope deposits against Tertiary bedrock and by scarps and some linear features developed on Pleistocene piedmont-slope deposits (Willden and Speed, 1968 #4370; 1974 #3645; Dohrenwend and others, 1992 #283). The range-fronts show a gentle topographic transition with the piedmont-slope of the Dixie Valley and, according to mapping by Dohrenwend and others (1992 #283), none of the faults show the topographic expression typical of range-front faults. dePolo (1998 #2845) reported that basal fault facets are absent along the range-front adjacent to this fault zone, and he related the absence of basal fault facets to relatively low Quaternary slip rates.
Age of faulted surficial deposits	Dohrenwend and others (1992 #283) assigned a late Quaternary age to faulted surficial deposits along this section of the fault zone.
Historic earthquake	
Most recent prehistoric deformation	late Quaternary (<130 ka) <i>Comments:</i> Although the timing of the most recent prehistoric faulting event is not well constrained, Dohrenwend and others (1992 #283) suggest a late Pleistocene (10-130 ka) time, based on faulted surficial deposits along this section of the fault zone.

Recurrence	
interval	
Slip-rate	Less than 0.2 mm/yr
category	
	<i>Comments:</i> No detailed data exists to determine slip rates for this
	fault. dePolo (1998 #2845) assigned a reconnaissance vertical slip
	rate of 0.01 mm/yr for the fault based on the presence of scarps on
	alluvium and the absence of basal facets. The late Quaternary
	characteristics of this fault (overall geomorphic expression,
	continuity of scarps, age of faulted deposits, etc.) support a low
	slip rate. Accordingly, the less than 0.2 mm/yr slip-rate category
	has been assigned to this fault.
Date and	2000
